

VE475 Homework 5

Liu Yihao 515370910207

Ex. 1 — RSA setup

1. In the RSA encryption and decryption, we use

$$ed \equiv 1 \pmod{\varphi(n)}$$

$$m^{ed} \equiv m \pmod{\varphi(n)}$$

This is based on the Euler's theorem, which has a condition that m and n be two coprime integers. So it is likely for n to be coprime with m .

2. Suppose $k = a\varphi(n)$, $a \in N^*$, and $m < n$.

(a)

$$\begin{aligned} m^k &\equiv (m^{\varphi(n)})^a \pmod{n} \\ &\equiv 1^a \pmod{n} \\ &\equiv 1 \pmod{n} \end{aligned}$$

So

$$m^k \equiv 1 \pmod{p} \quad \text{and} \quad m^k \equiv 1 \pmod{q}$$

- (b) First, if $\gcd(m, n) = 1$, according to (a), it's obvious that

$$m^{k+1} \equiv m \pmod{p} \quad \text{and} \quad m^{k+1} \equiv m \pmod{q}$$

Second, if $\gcd(m, n) = p$, so $\gcd(m/p, q) = 1$

$$\begin{aligned} m^{k+1} &\equiv p \left[\left(\frac{m}{p} \right)^{k+1} \pmod{q} \right] \pmod{n} \\ &\equiv p \left[\left(\frac{m}{p} \right)^{a(p-1)\varphi(q)+1} \pmod{q} \right] \pmod{n} \\ &\equiv p \cdot \frac{m}{p} \pmod{n} \\ &\equiv m \pmod{n} \end{aligned}$$

So

$$m^{k+1} \equiv m \pmod{p} \quad \text{and} \quad m^{k+1} \equiv m \pmod{q}$$

Third, if $\gcd(m, n) = q$, it is similar to the second case.

We can conclude that for any arbitrary m , $m^{k+1} \equiv m \pmod{p}$ and \pmod{q} .

3. (a) We know that $ed \equiv 1 \pmod{\varphi(n)}$, which means that $ed = k + 1$ where k is a multiple of $\varphi(n)$. According to part 2(b), we know that for any arbitrary m , $m^{k+1} \equiv m \pmod{p}$ and \pmod{q} , or we can say $m^{k+1} \equiv m \pmod{n}$, so $m^{ed} \equiv m \pmod{n}$,
- (b) From the previous calculation, we can find that for all $m < n$, no matter m and n are coprime or not, we can both find that $m^{ed} \equiv m \pmod{n}$, so that the RSA encryption and decryption can be performed. So we can conclude that it is not necessary that $\gcd(m, n) = 1$.

Ex. 2 — RSA decryption

$$n = 11413 = 101 \times 113$$

So we can find that $p = 101$ and $q = 113$, so $\varphi(n) = 11200$, and we should calculate d so that $ed \equiv 1 \pmod{\varphi(n)}$.

By applying the extended euclidean algorithm,

	q_i	r_i	s_i
0		7467	1
1		11200	0
2	$7467 \div 11200 = 0$	$7467 - 0 \times 11200 = 7467$	$1 - 0 \times 0 = 1$
3	$11200 \div 7467 = 1$	$11200 - 1 \times 7467 = 3733$	$0 - 1 \times 1 = -1$
4	$7467 \div 3733 = 2$	$7467 - 2 \times 3733 = 1$	$1 - 2 \times -1 = 3$

$$e \cdot 3 \equiv 1 \pmod{\varphi(n)}$$

So $d = 3$, then we can apply modulo exponentiation to the equation

$$m \equiv c^d \pmod{n}$$

i	d_i	power mod 11413
1	1	$1^2 \cdot 5859 \equiv 5859$
0	1	$5859^2 \cdot 5859 \equiv 1415$

So $m = 1415$.

Ex. 3 — Breaking RSA

1. When we decrypt an RSA ciphertext, we use $m \equiv c^d \pmod{n}$. When d is small, the decryption speed will be faster, so one would select short encryption or decryption keys.
- 2.

$$ed \equiv 1 \pmod{\text{lcm}(p-1, q-1)}$$

$$ed = K \cdot \text{lcm}(p-1, q-1) + 1, K \in \mathbb{N}$$

Suppose $G = \gcd(p-1, q-1)$, we can find

$$ed = \frac{K}{G}(p-1, q-1) + 1$$

$$\text{Let } k = \frac{K}{\gcd(K, G)}, g = \frac{G}{\gcd(K, G)},$$

$$ed = \frac{k}{g}(p-1, q-1) + 1$$

$$\frac{e}{pq} = \frac{k}{dg}(1-\lambda), \lambda = \frac{p+q-1-g/k}{pq}$$

Since $p \approx q \gg 0$, λ would be very small, then $\frac{e}{pq}$ is slightly smaller than $\frac{k}{dg}$, and

$$edg = k(p-1)(q-1) + g$$

Let $k_0 = \frac{k}{g}$ we can find

$$\varphi(n) = (p-1)(q-1) = \frac{ed-1}{k_0}$$

where $\frac{k_0}{d}$ converges to $\frac{e}{n}$.

Then we can apply continued fractions to get a list of approximate of k_0 and d , validate them and get the right d if it is small enough by the equation

$$x^2 - pq + n = 0$$

$$x^2 - (n - \varphi(n) + 1) + n = 0$$

$$p, q = \frac{n - \varphi(n) + 1 \pm \sqrt{(n - \varphi(n) + 1)^2 - 4n}}{2}$$

3. According to Wiener's theorem, decryption key should be larger than $\frac{1}{3}n^{1/4}$. For security considerations, it should be randomly selected from the safe range.
4. We apply continued fraction to n and e and get the following table:

i	a	k_0	d
0	0	0	1
1	4	1	4
2	9	9	37
3	1	10	41
4	19	199	816
5	1	209	857
6	1	408	1673
7	15	6329	25952
8	3	19395	79529
9	2	45119	185010
10	3	154752	634559
11	71	11032511	45238699
12	3	33252285	136350656
13	2	77537081	317940011

According to Wiener's theorem, $d < \frac{1}{3}n^{1/4} < 45$, so we can try data from $i = 1, 2$.

First we can guess that $k_0 = 1$, $d = 4$,

$$\phi(n) = \frac{ed - 1}{k_0} = 310148323$$

$$n - \varphi(n) + 1 = 7791689$$

$$(n - \varphi(n) + 1)^2 - 4n = 60709145712677$$

It is not a square number, so d is wrong.

Second we can guess that $k_0 = 9$, $d = 37$,

$$\phi(n) = \frac{ed - 1}{k_0} = \frac{2868871996}{9}$$

It is not an integer, so d is wrong.

Third, we can guess that $k_0 = 10$, $d = 41$,

$$\phi(n) = \frac{ed - 1}{k_0} = 317902032$$

$$n - \varphi(n) + 1 = 37980$$

$$(n - \varphi(n) + 1)^2 - 4n = 170720356 = 13066^2$$

$$p = \frac{37980 + 13066}{2} = 25523$$

$$q = \frac{37980 - 13066}{2} = 12457$$

$$n = 317940011 = 25523 \times 12457$$

Ex. 4 — Programming

In the ex3 folder, with a README file inside it.

Ex. 5 — Simple Questions

- 1.
2. No, it doesn't. Because the RSA problem is actually a factorization problem. If the attacker succeeded in factoring n , no matter how many exponents are chosen, the decryption method is the same.
- 3.

$$4 \cdot 516107^2 - 187722^2 \equiv 0 \pmod{n}$$

$$(2 \cdot 516107 - 187722)(2 \cdot 516107 + 187722) \equiv 0 \pmod{n}$$

$$1219936 \cdot 844492 \equiv 0 \pmod{n}$$

$$64866 \cdot 844492 \equiv 0 \pmod{n}$$

$$2 \cdot 3 \cdot 10811 \cdot 2^2 \cdot 211123 \equiv 0 \pmod{n}$$

We can find that 64866 must have a factor of n since $211123 < n$ (suppose n have only two factors according to RSA), and the factorization of 10811 is easy since it's small enough. We can try the primes smaller than $\sqrt{10811} (< 104)$ and find that it has a factor 19. Then we can deduce that $10811 = 19 \times 569$, where 569 is also a prime.

At last we can take 3, 19 and 569 as the possible factors of n , validate them and conclude that

$$n = 642401 = 569 \times 1129$$

4.

5.

$$(97 - 1) = 96 = 2^5 \times 3$$

So the generator x should satisfy that

$$x^{32} \not\equiv 1 \pmod{97} \quad \text{and} \quad x^{48} \not\equiv 1 \pmod{97}$$

$$x^{16} \not\equiv \pm 1, 35, 61 \pmod{97}$$

We can find that

$$2^{16} \equiv 61 \pmod{97}$$

$$3^{16} \equiv 61 \pmod{97}$$

$$4^{16} \equiv 1 \pmod{97}$$

$$5^{16} \equiv 36 \pmod{97}$$

So the smallest generator of $U(Z/97Z)$ is 5.

6. (a)

$$101 - 1 = 100 = 2^2 \times 5^2$$

$$2^{100/2} \equiv (2^{10})^5 \pmod{101}$$

$$\equiv 14^5 \pmod{101}$$

$$\equiv 100 \pmod{101}$$

$$2^{100/5} \equiv (2^{10})^2 \pmod{101}$$

$$\equiv 14^2 \pmod{101}$$

$$\equiv 95 \pmod{101}$$

Since $2^{50} \not\equiv 1 \pmod{101}$ and $2^{20} \not\equiv 1 \pmod{101}$, 2 is a generator of G .

(b)

$$\log_2 2 = 1$$

$$\log_2 24 = \log_2 3 + 3 \log_2 2 = 72$$

(c)

$$\log_2 24 = \log_2 125 = 3 \log_2 5 = 72$$

7.

$$(137 - 1) = 136 = 2^3 \times 17$$

$$\begin{aligned} 3^{136/2} &\equiv 3^5 \cdot (3^7)^9 \pmod{137} \\ &\equiv 243 \cdot (-5)^9 \pmod{137} \\ &\equiv 106 \cdot 12^3 \pmod{137} \\ &\equiv 106 \cdot 7 \cdot 12 \pmod{137} \\ &\equiv 136 \pmod{137} \\ 3^{136/17} &\equiv 3^8 \pmod{137} \\ &\equiv 3 \cdot -5 \pmod{137} \\ &\equiv 122 \pmod{137} \end{aligned}$$

Since $3^{68} \not\equiv 1 \pmod{137}$ and $3^8 \not\equiv 1 \pmod{137}$, 3 is a generator of $U(\mathbb{Z}/137\mathbb{Z})$.

$$\log_3 44 = 6$$

$$\log_3 2 = 10$$

$$\log_3 11 = \log_3 44 - 2 \log_3 2 = -14$$

So $x = 122$.

8. (a)

$$6^5 \equiv 10 \pmod{11}$$

So $6^5 = 10$ in $U(\mathbb{Z}/11\mathbb{Z})$

(b)

$$(11 - 1) = 10 = 2 \times 5$$

$$2^{10/2} \equiv 10 \pmod{11}$$

$$2^{10/5} \equiv 4 \pmod{11}$$

Since $2^5 \not\equiv 1 \pmod{11}$ and $2^2 \not\equiv 1 \pmod{11}$, 2 is a generator of G .

(c)
